ABSTRACT

One of the most dangerous types of cancer is leukemia which is predominant in children more than adult. The present study aimed to evaluate the chemopreventive activity of curcumin lipoate on tumor progression and hematopoiesis in the peripheral blood either in free form or conjugated with Zinc Oxide nanoparticles (ZnO-NPs) on the incidence of 7,12- dimethylbenz (a) anthrathene (DMBA) induced leukemiain female wistar rats. The activity of β2 microglobulin and CBC in addition to the activities of the most important free radical scavengers of the antioxidant defense system as well as malondialdehyde content were estimated. Liver function and kidney function markers were also determined for all groups. Cytopathological examination of peripheral blood of each group was also performed. The result of the present study revealed that, curcumin lipoate conjugated with ZnO-NPs, is more potent antitumor effect than in free form, as it normalizes most of the investigated parameters.

In conclusion, these results proved that, the conjugation form resulted in superadditive inhibitor effects on leukemic cells and this was well appreciated with the cytopathological alteration findings in the treated groups, these findings suggest that curcuminelipoate with Zinc-Oxide play an important role in prevention of leukemia.

Key words: Chemopreventive activity, curcumin lipoate, inhibitor, leukemia, nanotechnology

INTRODUCTION

One of the most dangerous types of cancer is leukemia which is predominant in children more than in adults. The behavior of leukemia is different than that of other cancers, which usually begin in major organs and ultimately spread to the bone marrow. Leukemia has two types, chronic and acute leukemia, the latter is rapidly progressing leukemia that starts in the bone marrow and causes large number of white blood cells to be produced and enter the blood stream⁴.

There are several types of leukemia (acute lymphoblastic leukemia ALL, acute myeloblastic leukemia AML, chronic lymphoblastic leukemia CLL and chronic myelogenous leukemia CML)². Although the risk for cancer is multifactorial and often seems to have confusing causes with no easy cures, a substantial portion of cancer incidence rates is believed to be due to environmental factors, including diet and exposure to certain chemicals³. The magnitude of the contribution to cancer of the bone marrow from exposure to environmental chemicals remains unclear. Nevertheless, one of the agents which has previously been identified to be responsible for the development of neoplasia is the polycyclic aromatic hydrocarbon (PAH), 7,12-dimethylbenz[a]anthracene (DMBA), which is an immuno-suppressor as well as a potent organ-specific carcinogen⁴. The mechanism by
which DMBA works relies on its capability of inducing oxidative stress and producing reactive oxygen species, which represent the key role in initiating the cancer process\(^{(5)}\).

The high prevalence of leukemia provides a strong rationale for identifying new compounds, both natural and synthetic, for use as cancer chemotherapeutic agents with limited side-effects. There is evidence that a variety of chemicals can inhibit, delay, and/or reverse cancer induced by either environmental insults or life style\(^{(6)}\).

Natural products are the best way to prevent or treat tumor progression. Curcumin lipoiate proved that it is one of the best way to prevent cancer. The chemical composition of curcumin lipoiate consists of conjugation of curcumin with lipoic acid which are very strong natural antioxidants. Curcumin lipoiate is relatively non toxic with a no effect level.

Deng \textit{et al.}\(^{(7)}\) indicated that nanotechnology has an advantage in cancer therapy and he found that metallic nanoparticles especially Zinc-Oxide nanoparticles activate neural stem cell apoptosis by activating Fas, caspase-8 and induce mouse epidermal JB6 cell apoptosis. On the other hand, some investigations showed that nanoparticle supplementation can o prevent cancer occurrence. Metal oxide nanoparticles, including zinc oxide, are versatile platforms for biomedical applications and therapeutic intervention\(^{(8)}\). In this regard, studies have been reported that ZnO-NPs induce selective cytotoxic action on mammalian cancer cells in a cell-specific and proliferation-dependent manner which suggests an exciting potential for ZnO-NPs as novel alternatives to cancer therapy\(^{(9)}\). However, there are several issues which need to be resolved before translation of zinc oxide nanoparticles into medical use, including a better understanding of the mechanism of their selective cytotoxic action\(^{(9)}\).

This study aimed to examine the effects of chemo-preventive activity of curcumin lipoiate on tumor progression, chemotherapeutic efficacy and hematopoiesis in the peripheral blood either in free form or conjugated with the ZnO-NPs.

**MATERIALS AND METHODS**

**Experimental animals and materials:**

Wister female rats weighing 50±20 g were obtained from Nile Company at Amiria, Cairo. Rats were housed in plastic cages, five rats in each cage in freely fed of rats diet and excess of drinking water at temperature 22±3 C\(^{0}\) at the National Center for Radiation Research and Technology (NCRRT), Cairo.

**Chemicals:**

All chemicals were obtained from Sigma Aldrich Company, Egypt.

**Curcumin lipoiate**, compound was prepared by professor Abdelfattah Badawi, prof. of applied chemistry in Egyptian Petroleum Research Institute (EPRI).

**Biosynthesis of curcumin lipoiate according to Kappe\(^{(10)}\):**

**First**, approximately 2.4mmol curcumin was weighed and dissolved in 50 ml dioxane. Following the addition of 0.3 : 0.73 g pyridine, 4.8 mmol Lipoic acid was added to the system dropwise. The system was allowed to react for 2 hours in an ice water bath. The reaction was monitored by TLC, which was developed with 3:1 chloroform/ethyl acetate. Second, the product obtained was poured into 40 ml petroleum ether for filtering. The resultant precipitate was dissolved into 30 ml ethyl acetate. The solution was washed twice with 20 ml of 1 mol/L hydrochloric acid solution and once with saturated sodium carbonate solution. The resultant material was dried for 2 h by adding 3 g anhydrous sodium sulfate. Subsequently filtration was performed and the filtrate was removed by spinning. Then the crude product curcumin Lipoiate was obtained. Third, the above crude product curcumin Lipoiate was loaded onto a silica gel column and diluted with 7:1 petroleum
ether/chloroform. The target product was collected and dried in vacuum to obtain approximately 1.67 g final product, i.e. curcumin Lipoiate. Fourth, curcumin Lipoiate prepared by this example was confirmed to possess an expected structure of curcumin Lipoiate by using the micro elemental analysis method as follow:

Biosynthesis of curcumin lipoiate/ ZnOnano-composite:

Two stock solutions of standard Curcumin Lipoiate and its conjugate ZnO-NPs were prepared. Approximately 0.0373 gm/ml Curcumin Lipoiate was dissolved in dimethyl sulfoxide (DMSO), 0.0373 gm/ml ZnO was suspended in (DMSO). The 2 solutions were mixed and kept in dark glass containers and stored at 4°C. A series of dilutions were carried out to achieve a final concentration of curcumin lipoiate (10, 25, 50, 75 and 100μg/ml)

Methods:
Evaluation of antitumor efficacy of the tested compounds:

The present study was designed to comprise a series of in vitro and in vivo investigations as following;

In vitro studies:
Viability test:
Trypan blue exclusion method (1hour experiment)

The results of this method easily distinguish between viable and nonviable cells, since the former are unstained, small, and round, while the latter are stained and swollen. The traditional method of performing trypan blue cell viability analysis involves manual staining and use of a hemocytometer for counting. Ehrlich Ascites Carcinoma (EAC) (mouse tumor) was used to investigate the antitumor activity of curcumin lipoiate and nano-zinc oxide suspension in curcumin lipoiate. The parent line of EAC was supplied through the National Cancer Institute (NCI), Cairo University. The tumor line was maintained in female Swiss albino mice by intraperitoneal transplantation of 2.5 x 10^6 cells. The antitumor effect and inhibitory concentration 50 (IC_{50}) of curcumin lipoiate and a combination of (curcumin lipoiate+ZnO-NPs) were investigated on the viability of Ehrlich Ascites Carcinoma (EAC).

In vivo study:
Determination of LD50:

Traditionally acute oral toxicity testing has focused on determining the dose that kills half of the animals (i.e., the median lethal dose or LD50), the timing of lethality following acute chemical exposure, as well as observing the onset, nature, severity, and reversibility of toxicity.

The optimum selected dose for evaluating the in vivo antitumor activity of the novel synthesized curcumin lipoiate was calculated as (1/12) of it’s LD50 value, which was 50mg/kg (b.w.). Whereas, curcumin lipoiate combined to ZnO nanoparticles were used in a dose equivalent to approximately 50% of the dose selected for curcumin lipoiate, this equals 25mg/kg (b.w.). The in-vivo study was carried out using these doses for experiment. Fresh solutions of the tested compounds were prepared in sterile saline, according to their chosen doses, just prior their administration.
Work-flow design:
In the present study animals were divided into six groups (each group consisting of 10 rats), which were recognized as follows:
G (1) (Normal control): This group comprised normal rats received oral doses of DMSO. Animals were left for 3 months then they were scarified.
Group (2) (Curcumin lipoiate): Animals were intraprotonially injected with curcumin lipoiate three times a week (day other day) in a dose of 50 mg/kg b.w. till the end of the experiment.
Group (3) (Curcumin lipoiate + ZnO-NPs): Animals were intraprotonially injected with curcumin lipoiate + ZnO-NPs three times a week in a dose of 25 mg of cur.lip+ZnO/lg/kg b.w. till the end of the experiment.
G(4) (DMBA): Animals were intravenously injected with 7, 12 dimethyl benz (a) anthracene (DMBA) two times a week in a dose of 35 mg/kg b.w.(15) till the end of the experiment.
Group (5) (DMBA + Curcumin lipoiate): Animals were intraprotonally injected with curcumin lipoiate as mentioned in group (2) as well as the injection of DMBA as described in group (4) until the end of the experiment (three months).
G(6) (DMBA + Curcumin lipoiate + ZnO-NPs): Animals were intraprotonially injected with curcumin lipoiate + ZnO-NPs as described in group (3) as well as the injection of DMBA as mentioned in group (4).

Experimental protocol (blood sampling and plasma preparation):
The animals were sacrificed after 3 months from the beginning of cancer induction with or without different protection. Whole blood was collected from heart by syringes and divided into two portions, the first portion was whole EDTA blood and used for the determination of complete blood picture (CBC) automated(16). Also, whole blood used to measure antioxidants status and lipid peroxidation were determined colorimetrically as reduced glutathione content (GSH) and glutathione peroxidase (GPx) measured(17), superoxide dismutase (SOD) (18) and catalase(19) and determination of lipid peroxide level (LPx)(20). Liver function indicators were determined colorimetrically as total protein (TP)(21) and albumin(24). Alanine aminotransferase (ALT) and aspartate aminotransferase (AST)(22), alkaline phosphatase (ALP) (23) and γ Glutamyl Transferase (GGT)(15) also were carried out. Kidney function indicators as Creatinine(25), and blood urea(26) were estimated using a diagnostic kit. The other portion was centrifuged and separated plasma was used for the determination of the following: β2 microglobulin using ELISAk it which based on the principle of a solid phase enzyme-linked immune sorbent assay (ELISA)(16).
Cytopathological examination: was carried out from peripheral blood smear by staining it with Giemsa stain to be examined under microscope(27).
Statistical analysis: All statistical analyses were performed using computerized software, SPSS program (Statistical Packages for Social Sciences, version 15.0)(28, 29). Data were analyzed using a one-way analysis of variance (ANOVA), followed by least significant difference (LSD) multiple comparisons test, when an overall significance was indicated by the P-value. The level of significance was set at $P < 0.05$ in all cases. All data are reported as the mean ± S.D. for six rats per each group.
Evaluation of chemopreventive activity of curcumin lipoate as an inhibitor of leukemia using nanotechnology

RESULTS

The efficiency of curcumin lipoate alone or conjugated with ZnO-NPs evaluated by both in vitro and in vivo studies.

In vitro study:

The results were indicated in Table (1). The 50% growth inhibitory concentration (IC$_{50}$) values for free curcumin lipoate and its combination with ZnO-NPs were estimated from the available cytotoxicity. The novel curcumin lipoate+ZnO-NPs exhibited the strongest in vitro anticancer activity against Erlich Ascited Carcinoma (EAC), it recorded the lowest IC$_{50}$ value (20µg/ml) comparable to that of free curcumin lipoate (50µg/ml) against (EAC).

In vivo study:

Biochemical Analyses:

whole blood Antioxidant defense system:

After three months of treatment, antioxidant activity levels (GSH, GPx, SOD and CAT) were shown to be decreased significantly in the DMBA- induced group (G 4) relative to control group, while there was an improvement in antioxidants levels observed in the treated groups either with urumin lipoate alone or with its conjugate ZnO NPs compared with the DMBA treated model group. More improvement was observed in group treated with curumin lipoate + ZnO NPs comparable with its free form (Table 2).
curcumin lipoate and its combined form with ZnO-NPs on whole blood antioxidant defense system:

Each value represents the mean of 6 records ± S.D.

a: significant different vs normal control group.
b: significant different vs DMBA administrated group.

Lipid Peroxidation:
MDA level was increased significantly in the DMBA treated model relative to control group, but decreased in groups treated with curcumin lipoate and its conjugated form with ZnO-NPs compared with the DMBA model group (Table 3).

β2 microglobulin levels:
Results in Table (3) showed that, DMBA-treated group displayed a significantly increase in β2 microglobulin relative to control group (which would be due to presence of tumors). On the contrary, curcumin lipoate and curcumin lipoate/ZnO supplementation significantly decreased the β2 microglobulin level. Such that, β2 microglobulin was elevated in the DMBA-model compared to both the treated group and the normal control groups.

Complete blood picture (CBC):
Evaluation of chemopreventive activity of curcumine lipoiate as an inhibitor of leukemia using nanotechnology

The complete blood picture (CBC) [white blood cells (WBCs) (10^3/mm^3), Red blood cells (RBCs)(10^6/mm^3), hemoglobin (Hb) (g/dl), Platelets (Plat) (10^3/mm^3), hematocrit (HCT) (%), Mean Corpuscular Volume (MCV) (fl), Mean Corpuscular Hemoglobin (MCH) (pg), Mean Corpuscular Hemoglobin Concentration (MCHC) (g/dl), lymphocytes (%), Neutrophiles (%), Monocytes (%) & Eosinophiles (%)] were determined in female Wister rats. Data presented in Tables (4, 5) showed a highly significant decrease in WBCs count (% of Neutrophiles, % of Monocytes, % of Eosinophiles), RBCs count, hemoglobin concentration, Platelets count and indices of RBCs (HCT, MCV, MCH and lymphocytes) in group with leukemia (G4) compared to control group (G1), but MCHC percentage showed a significant change with control. Whereas, a highly significant increase in lymphocytes percentage was observed in DMBA treated groups either with curcumin lipoiate or curcumin lipoiate + ZnO (P<0.001) compared to control. Meanwhile, in all studied groups of animals with leukemia showed a significant improvement with treatment either by curcumin lipoiate (G5) or curcumin lipoiate + ZnO (6) in WBCs count, % Neutrophiles, % Monocytes, % Eosinophiles, RBCs count, hemoglobin concentration, platelets count and indices of RBCs (HCT, MCV, MCH and MCHC). As well as for platelets count, there was a non significant change in platelets count (p>0.05) in group supplemented with curcumin lipoiate + ZnO (G3) when compared to control group.

Evaluation of chemopreventive activity of curcumin lipoiate as an inhibitor of leukemia using nanotechnology

Determination of liver functions:
Liver function tests [aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), \( \gamma \) Glutamyltransferase (GGT), total protein (TP), and Alb] were determined in plasma. The results in table (7) showed that, a significant increase in the activity of ALT, AST, ALP, GGT, albumin and TP of leukemic group without treatment compared to control. There was an improvement in liver enzymes activities in leukemic animals treated with Cur.lipoiate and Cur.lipoiate-ZnO when compared with leukemic group.

Table (7): Effect of individual curcumin lipoiate and its combined form with ZnO-NPs nanoparticles on plasma levels of liver function indicators.

Each value represents the mean of 6 records \( \pm \) S.D.

a: significant different vs normal control group.
b: significant different vs DMBA administrated group.

Cytopathological examination:
Examination of peripheral blood smears stained with Giemsa stain indicated:
A: normal blood smear (control) with normal blood cells (c).
B: blood smear of leukemic group, with blast cells (b) that represent an average 74% of the total WBCs count.

Legends of Figure
Figures (A, B, C, D, E, F): Photographs of peripheral blood smear of different groups, stained with Giemsa stain, Magnified X 100.

A: Control group with normal blood cells (c).
B: Leukemic group, with blast cells (b).
C: Leukemic group supplemented with curcumin lipoiate, showing improved blood film, without blast cells.
D: Leukemic group supplemented with curcumin lipoiate+ ZnO-NPs, showing improved blood film, without blast cells.
E: Group supplemented with curcumin lipoiate NPs, showing normal blood cells.
F: Group supplemented with curcumin lipoiate + ZnO-NPs, showing normal blood cells.
A: Blood smear concerning normal control.

B: Blood smear concerning leukemic group.

C: Blood smear concerning leukemic group supplemented with curcumin lipoate alone.

D: Blood smear concerning leukemic group Supplemented with curcumin lipoate + ZnO.

E: Blood smear concerning group with Curcumin lipoate only.

F: Blood smear concerning group with curcumin lipoate + ZnO.
Evaluation of chemopreventive activity of curcumin lipoate as an inhibitor of leukemia using nanotechnology

**DISCUSSION**

There is increasing evidence that cancer and other mutation related diseases can be prevented not only by avoiding exposure to recognized risk factors but also by favoring the intake of protective factors and by modification of defense and DNA repair mechanisms of the host organism. This strategy referred to as chemoprevention and it is realized by means of suitable pharmacological agents and/or by dietary factors. In the present study, the cytotoxic-effects and the biological activities of curcumin lipoate and curcumin lipoate combined with ZnO-NPs as antitumor agents were evaluated both in vitro and in vivo studies. The in vitro study was conducted to evaluate the cytotoxic effects of the tested compounds on the ErlichAscite Carinoma (EAC) using Trypan blue assay. The results revealed that both curcumin lipoate and curcumin lipoate+ZnO-NPs affect cell viability of (EAC). These results are in harmony with early studies which observed in vitro anticancer activity of curcumin compounds against many cancer cell lines. Referring to the 50% growth inhibitory concentration (IC50) values, the novel curcumin lipoate conjugated with ZnO-NPs exhibited the highest in vitro tumoricidal effect against (EAC) which is dose-dependent. Where, it recorded the lowest (IC50) comparable to that of curcumin lipoate alone. These results may suggest that, the action of curcumin lipoate+ZnO-NPs resulted in super-additive cytotoxic effects on leukemic cancer cells.

The current in vivo study aims to investigate an antitumor activity of curcumin lipoate which of natural origin either in free form or conjugated with ZnO-NPs. Breast tissue and bone marrow may be a major target for the toxicological effects of a variety of lipophilic carcinogens such as polycyclic aromatic hydrocarbon (PAH) respectively. Metabolic activation of DMBA,a member of the PAH family, by cytochrome P450 (CYP) enzymes produces radical cations, free radicals and oxygenated metabolites (epoxides) that bind directly to DNA, presumably leading to genetic mistakes that result in cancers. Numerous studies have shown that 7,12-dimethylbenz(a)anthracene (DMBA) can be used to induce experimental leukemia in rats and that this process involves disruption of tissue redox balance; in turn, this suggests that biochemical and pathophysiological disturbances may result from oxidative damage. The extent of oxidative stress was evaluated on the basis of its foremost biomarkers such as; activities of some antioxidant defense enzymes and lipid peroxidation end products (MDA, a byproduct of lipid peroxidation). Oxidative stress, resulting from ROS generation, is one out of several etiological and pathophysiological factors implicated in carcinogenesis. Kaur et al. reported that, it is considered to be implicated in the path of physiology of breast cancer. Under normal circumstances, ROS are efficiently kept in check by body's elaborate antioxidant defense system which keeps equilibrium between ROS formation and dissipation. However, such protective mechanisms can be broken easily by environmental exposure to chemicals, such as DMBA, which disrupt the pro-oxidant–antioxidant balance, leading to cellular anomalies. Antioxidant enzymes act as the primary line of defense against ROS which suggest their usefulness in estimating the risk of oxidative damage induced during carcinogenesis. Moreover, the study of Arulkumaran et al. inferred that, the biochemical alterations observed in cancer bearing animals may be due to the reduction of antioxidants levels (GSH, GPx, SOD and CAT) following carcinogen (DMBA) administration; which may be due to the utilization of antioxidants to scavenge the free radicals. The decreased level of CAT observed in cancer-bearing animals may be due to the utilization of antioxidant enzymes in the removal of H2O2 by DMBA. Moreover, decreased level of CAT activity was measured in patients of leukemia and breast cancer diseases. Results of the present work revealed a significant
Ahmed Salem et al.

increase in the GSH content in both tumor-free and tumor-induced rat groups treated with either our novel curcumin lipoiate alone or combined with ZnO-NPs compared to DMBA group. Similarly, GPx activity also significantly increased in tumor-induced rat groups treated with curcumin lipoiate alone and curcumin lipoiate+ZnO-NPs compared to DMBA group. Our results revealed that, a significant increase of SOD activity in rat groups treated with either curcumin lipoiate and curcumin lipoiate+ZnO-NPs compared to DMBA group. Furthermore, CAT activity was significantly increased in both rat groups treated with DMBA+curcumin lipoiate and DMBA+curcumin lipoiate+ZnO-NPs with respect to DMBA-treated rat group and these results agreed with previous reports.(43).Oxidative stress, especially lipid peroxidation is known to be involved in carcinogenesis (45). Increased levels of lipid peroxidation products play a role in the early phases of tumor growth. So that, in the present study, injection of DMBA intravenously to female Wister rats has been proved to induce significant deleterious changes in antioxidant status. As the results revealed a significant increase in MDA level compared to normal control, these findings were in agreement with previous studies which reported that tumor incidence could cause antioxidant disturbances, acceleration in lipid peroxide, and decrease in GSH content and increase in γ-glutamyl transpeptidase activity (46).The biochemical findings of DMBA injected group showed noticed elevation in the beta-2 microglobulin, compared to the control group indicating that there is a cancer in the DMBA injected group due to carcinogenicity of DMBA. Our results revealed that, DMBA group pretreated with curcumin lipoiate showed a marked depletion in MDA level as well as β2 microglobulin level compared to the DMBA group.Complete blood picture parameters especially platelets, hemoglobin, WBCs,, RBCs and RBCs indices were depleted in DMBA group as agreed with previous study(46). While, there was an improvement in these parameters upon its treatment with curcumin lipoiate and its conjugate ZnO-NPs.Also, differential counting improved in case of pre-treated groups with curcumin lipoiate and its conjugate ZnO-NPs in contrast with DMBA group.Also, liver and kidney functions like (ALT, AST, ALP, TP, GGT, Albumin, Urea and Creatinine) were improved in treated groups with our novel compound more than non treated groups.The results of our study revealed that, curcumin lipoiate and its conjugate ZnO-NPs showed anti-tumor and hematopoietic effect through it can inhibits over cell proliferation hence, it can prevents formation of blast cell.

In the present study cytopathological findings revealed that pretreatment with curcumin lipoiate and its conjugate ZnO prevented tumor induction in blood as it prevents leukemia but the results of curcumin lipoiate + ZnO is more better than of curcumin lipoiate only. There were noticeable normal blood cells in the peripheral blood smears, with normal cell counts, no presence of a typical cells and no evidence for blast cells, as curcumin is potent antiangiogenic agent. In the present study, the results indicated that the antitumor activity of the curcumin lipoiate was significantly enhanced by its conjugate ZnO nanocomposite.

Hence, Combination of different sized ZnO nanoparticles curcumin lipoiate could have synergistic cytotoxic effect on leukemic cancer cells, indicating the great potential of ZnO-NPs in relevant clinical and biomedical application. From the above mentioned results it can be concluded that, pretreatment of DMBA group with ccurcumin lipoiate + ZnO-NPsShowed more improvement in antioxidant state than that of curcumin lipoiate alone.
